Abstract
In this paper, based on an amalgamated duplication of a ring along an ideal, we will construct the amalgamated duplication of an unitary normed algebra $X$ along its proper ideal $I$ (i.e. $X \bowtie I$). Then we will discuss about its Banach conditions and abstract properties. Mainly we have proven that if $X$ be a Banach algebra and $I$ be its closed ideal then $X \bowtie I$ will be Banach algebra too. As well, we have shown that its completion and ideals based on original normed algebra $X$. Finally some more aspects to expend these results for generalized normed algebras are given.

Keywords: Amalgamated duplication, Unitary normed Algebra, Banach Algebra,*-algebra.

1. Introduction
In recent years, there have been several investigations \cite{9,8,2,6} to find properties of the amalgamated duplication of a ring along an its proper ideal. This concept first was presented by \cite{9}. More details, If $R$ is a commutative ring with identity and $I$ be a proper ideal of $R$, the following definition, which is as a sub-ring of $R \times R$
\begin{equation}
(1.1) \quad R \bowtie I := \{(x,y) : x, y \in R \& y - x \in I\},
\end{equation}
was proposed by \cite{9} as so called the amalgamated duplication of ring along an its ideal. It can be shown that the above structure is a extension for idealization which was originally introduced by \cite{10} (See \cite{9,8} to more details).
Mathematical properties and applications of this type of extensions have been a motivation for some other papers (See e.g. \cite{1,3,11,5}).
Here, we have an attempt to extend such approach in operator theory. More details, we will define the $X \bowtie I$ for the unitary normed algebra $X$ and its proper ideal $I$, then we will show with some appropriate $d$ it forms a normed algebra as well. Then, we will discuss about its some aspects like Banach conditions, abstract properties and closure and closed aspects. Mainly we will prove in section 3 that $X$ is an unitary Banach algebra if an only if $X \bowtie I$ is an unitary Banach algebra and $I$ is closed, as well as $X$ is Noetherian if and only if $X \bowtie I$ is Noetherian and $X \bowtie I = X \bowtie I$. Moreover, to clear these aspect we will use some applicable illustrations, too. Roughly speaking, this paper gives most selected aspects of amalgamated duplication for normed algebras as well as carrying that construction in operator theory in both abstract and normed scopes. More importantly, present paper organized as follows: In Sec 2, some basic concept about normed algebras as well as constructing amalgamated duplication of a unitary normed algebras along an ideal will given. Sec 3 will be devoted to main results for normed rings. Sec 4, discuses mainly about expanding this construction for generalized normed algebra and expressing this results for normed rings.

2. Preliminary

In this section we will recall some basic notions from the operator theory, i.e. normed algebra and its aspects. The reader is referred to [7] for further details, and [3] for modern expositions and further developments.

Definition 2.1. A normed space $X$ that is simultaneously an algebra with respect to a product operation $X \times X \to X$, say $(x, y) \mapsto xy$, such that $\|xy\| \leq \|x\| \cdot \|y\|$ is called a normed algebra. If a normed algebra possesses an identity $I$ such that $\|I\| = I$, then it is a unital normed algebra (or a normed algebra with identity).

Through this paper let $X$ be an unitary commutative normed algebra with norm $\|\cdot\|$ and $I$ is a proper ideal of that. We can show the following set $X \bowtie I := \{(x, y) : x, y \in X \land y - x \in I\}$, with ordinary addition and multiplication is provide a new unitary algebra. More details, since $(x_1, y_1) + (x_2, y_2) = (x_1 + x_2, y_1 + y_2)$ and $\alpha(x, y) = (\alpha x, \alpha y)$ for every $(x_1, y_1)$ and $(x_2, y_2)$ of $X \bowtie I$ and $\alpha$ in $F$ are belong to $X \bowtie I$, so it forms a subspace of $X \times X$. As well $(x_1, y_1)(x_2, y_2) = (x_1 x_2, y_1 y_2 + x_2 y_1 - x_1 y_2 + x_2 y_1 - x_1 y_2)$, is belong to $X \bowtie I$. So we can conclude $X \bowtie I$ is a sub-algebra of $X \times X$ with identity $(I, I)$.

Now, we can define the real-valued function $d : X \bowtie I \to R$

\[
(2.1) \quad (x, y) \mapsto \|x\| + \|y\|
\]

where $\|\cdot\|$ is norm of $X$. It is easy to check that $d$ is defined a norm on $X \bowtie I$. Moreover, we have $d((x_1, y_1)(x_2, y_2)) = d((x_1 x_2, y_1 y_2 + x_2 y_1 - x_1 y_2 + x_2 y_1 - x_1 y_2))$

\[
\leq \|x_1\| + \|x_2\| + \|y_1\| + \|y_2\| = d((x_1, y_1)) + d((x_2, y_2))
\]

So, $X \bowtie I$ with $d$ forms an normed algebra which can be named as amalgamated duplication of unitary normed algebra along an ideal.

Remark 2.2. As we can see through norm (2.1) $X \bowtie I$ is not unitary normed algebra. Actually we find $d(I, I) = \|I\| + \|I\| = 2$.

Remark 2.3. We can define $d$ in other ways. For example as form $d'((x, y)) = \|x\| + d''((x, x + i)) = \|x\| + \|i\|$. As we can show $X \bowtie I$ with $d'$ is unitary semi-normed algebra and with $d''$ is unitary semi-normed algebra, too. But in this paper we have chosen $d$ as form (2.1) in order to have a normed algebra.

To finish this section we point out that every element of $L(X)$ (linear space of all linear transformations on $X$) induces an element for $L(X \bowtie I)$. More details, consider the following maps $\pi : X \bowtie I \to X$ & $(x, x + i) \mapsto x$, 

76
3. Main title

Through this section consider $X$ as an arbitrary unitary normed algebra with proper ideal $I$.

First, we want to investigate that whether $X \bowtie I$ is Banach algebra for the Banach algebra $X$. For this, we will begin with following elementary definitions.

**Definition 3.1.** A Banach algebra is a normed algebra that is complete as a normed space.

**Definition 3.2.** A metric space $X$ is complete if every Cauchy sequence in $X$ is a convergent sequence in $X$.

Next result mainly is investigated Banach conditions for $X \bowtie I$:

**Theorem 3.3.** $X$ is an unitary Banach algebra if an only if $X \bowtie I$ is an unitary Banach algebra and $I$ is closed.

Proof. Let $\{(x_n, y_n)\}$ be a Cauchy sequence in $X \bowtie I$ with $X$ as a Banach algebra. Since $X$ is Banach, So sequence $\{x_n\}$ and $\{y_n\}$ are convergent. As a result sequence $\{(x_n, y_n)\}$ is convergent (say to $(x, y)$). Moreover, if we consider new subtraction sequence $\{y_n - x_n\}$ trivially it converges to $y - x$. Since $I$ is a closed ideal, we can conclude $y - x$ is in $I$ and as a result $(x, y)$ is lying in $X \bowtie I$. Hence, $X \bowtie I$ is a Banach algebra.

Conversely, Let $X \bowtie I$ be Banach algebra and $\{x_n\}$ be a cauchy sequence in $X$. So, sequence $\{(x_n, x_n)\}$ is a Cauchy in $X \bowtie I$ and it is convergent (say $(x, x)$). As a result $\{x_n\}$ is convergent and hence $X$ is Banach as well.

We know that any Banach algebra (whether it has an identity element or not) can be embedded isometrically into a unitary Banach algebra $X_e$ so as to form a closed ideal of $X_e$. So, the two following results are hold:

**Corollary 3.4.** If $X$ be a Banach algebra and $I$ be its proper closed ideal, then $X \bowtie I$ can be embedded in an unique unitary Banach algebra.

**Corollary 3.5.** If $X$ be a Banach algebra whether it has an identity element or not, then $X_e \bowtie X$ is unitary Banach algebra.

**Example 3.6.** Let $X$ and $Y$ as Banach algebras. In [6] was shown that $B(X, Y)$ (the set of all bounded linear transformation from $X$ to $Y$) is a Banach algebra and $B_e(X, Y)$ is its closed ideal, so by above theorem the amalgamated duplication $B[X, Y] \bowtie B_e(X, Y)$ forms a Banach algebra as well.

Next proposition provide more Banach amalgamated algebras:

**Proposition 3.7.** If $X$ be a Banach algebra and $I$ be a maximal regular ideal, then $X \bowtie I$ is Banach algebra.

Proof. In [13] was proven that maximal regular ideals are closed. So using that fact the proof is clear.

One of the most important properties that must be considered for $X \bowtie I$ is form of its closure. The closure of any normed algebra $X$ is defined as a set consists of all points in $X$ plus the limit points of $X$ and shown by $\bar{X}$ The following preposition mainly is investigated closure of $X \bowtie I$ using closure of $X$ and $I$.

**Proposition 3.8.** We have:
In fact, if and 

The following proposition is devoted to relations between involutions of 

Proposition 3.10. Let be the -algebra with involution and be its proper ideal, then we can construct involution for , if we have .

Proof. Consider the following map on 

\[ x_n \rightarrow x \text{ and } i_n \rightarrow i, \]

so is belong to and is belong to . As a result is in 

Conversely, consider .

Consider .

The concept of -algebra plays an important role in algebra theory [12]. -algebra is an algebra equipped with an algebra involution and an algebra involution on an algebra is an involution on such that for all , in and all , in , we have

\[
(\lambda x + \mu y)^\ast = \lambda x^\ast + \mu y^\ast \\
(xy)^\ast = y^\ast x^\ast.
\]

(3.2)

The following preposition is devoted to relations between involutions of and , and to condition of constructing as the *-algebra using involution of .

Proposition 3.10. Let be the -algebra with involution and be its proper ideal, then we can construct involution for , if we have .

Proof. Consider the following map on :

\[ \alpha : X \bowtie I \rightarrow X \bowtie I \]

\[ (x, x + i) \mapsto (x^\ast, x^\ast + i^\ast). \]

since so the above map is well defined. For conditions (3.2) we get

\[
\alpha (\lambda (x, x + i) + \mu (y, y + J)) = \alpha (\lambda x + \mu y, \lambda x + \mu y + \lambda i + \mu j)
\]

\[ = (\lambda x + \mu y)^\ast, (\lambda x + \mu y)^\ast + (\lambda i + \mu j)^\ast
\]

\[ = (\lambda x^\ast + \mu y^\ast, \lambda x^\ast + \mu y^\ast + \lambda i^\ast + \mu j^\ast)
\]

\[ = \lambda (x^\ast, x^\ast + i^\ast) + \mu (y^\ast, y^\ast + j^\ast)
\]

\[ = \lambda x^\ast + \mu y^\ast + \lambda i^\ast + \mu j^\ast
\]

\[ = \lambda (x, x + i) + \mu (y, y + j),
\]

and

\[
\alpha (x, x + i)(y, y + j) = \alpha ((xy, xy + ij)) = ((xy)^\ast + (xy)^\ast + (ij)^\ast)
\]

\[ = ((y^\ast x^\ast, y^\ast x^\ast + j^\ast i^\ast))((x^\ast, x^\ast + i^\ast))
\]

\[ = \alpha ((y, y + j) (x, x + i)).
\]

Hence the map (3.3) is an involution on and as a result will be an *-algebra.

Large of important results for can be inherited from detected properties of (i.e. amalgamated duplication of a ring along an its ideal) which were established in [2,4,8,9]. In continuation some of them are given.

Theorem 3.11. is Noetherian if and only if is Noetherian.

Proof. It is not difficult to see that, if are the projections of on , then ; hence, if , then .

In fact, if is Noetherian, then also is Noetherian, hence is finitely generated as -module and so is Noetherian; conversely, if is Noetherian, then (To more details see [8]).
Theorem 3.12. Let $P$ be a prime ideal of $X$ and set:
\[
P_0 = \{(p, p + i) | p \in P, i \in I \cap P\},
\]
\[
P_1 = \{(p, p + i) | p \in P, i \in I\},
\]
\[
P_2 = \{(p + i, p) | p \in P, i \in I\}.
\]
(3.4)

- If $I \subseteq P$, then $P_0 = P_1 = P_2$ is a prime ideal of $X \bowtie I$ and it is the unique prime ideal of $X \bowtie I$ lying over $P$.
- If $I \not\subseteq P$, then $P_1 \neq P_2$, $P_1 \cap P_2 = P_0$ and $P_1$ and $P_2$ are the only prime ideals of $X \bowtie I$ lying over $P$.

Corollary 3.13. If $X$ is local, with maximal ideal $m$, then $X \bowtie I$ is local with maximal ideal
\[
m_0 = \{(x, x + i) | x \in m, i \in I\}.
\]

4. More discussions

As before, in this section we have an attempt to extend our new construction to generated normed algebras as well as express that for noremd rings. For this we will begin with two essential definitions:

**Definition 4.1.** A generalized normed algebra $X$ is an abstract algebra with family of norms which satisfy in the following condition:
\[
\|xy\| \leq \|x\| \cdot \|y\|,
\]
for every $x$ and $y$ in $X$ and for every norm $\|\cdot\|$ in that family.

**Definition 4.2.** A normed ring is a linear algebra $R$ over the complex numbers or the real numbers with a norm having, besides the usual properties of a norm, also the ”ring” property
\[
\|xy\| \leq \|x\| \cdot \|y\|,
\]
for every $x$ and $y$ in $R$.

Using the method which we allied in Sec.2, we can equip an amalgamated duplication structure to both normed ring and generalized normed algebra. As well all established statements can be extended to both normed ring and Generalized normed algebra.

For instance, we have:

**Theorem 4.3.** Let $X$ be an Generalized unitary normed algebra. Then $X$ is Banach if and only if $X \bowtie I$ is an Generalized unitary Banach algebra and $I$ is closed.

and

**Proposition 4.4.** Let $R$ be a normed ring, then we have:
\[
R \bowtie I = \bar{R} \bowtie \bar{I}
\]
(4.2)
Without any doubt, These extensions makes the work of studying the amalgamated duplication of an unitary normed algebra more expediently.

Conclusions

In this work, starting with an unitary normed algebra $X$ and its proper ideal $I$, we have introduced new construction $X \bowtie I$ which can be named amalgamated duplication of an unitary normed algebra along an its ideal. And we proved that essential and sufficient conditions for Banach and abstract proprieties of it like ideals, primes and Noetherian. As well, some aspect and generalization of that to $C^*$-algebras and normed rings have expressed. These make the work of studying the amalgamated duplication more expediently.
