Communicated by X. Qin

Abstract

In this paper, we consider a new parallel algorithm combining viscosity approximation methods to approximate the multiple-set split common fixed point problem governed by demicontractive mappings, and get the generated sequence converges strongly to a solution of this problem. The results obtained in this paper generalize and improve the recent ones announced by many others. ©2017 All rights reserved.

Keywords: Multiple-set split equality common fixed-point problem, demicontractive mapping, strong convergence.

1. Introduction

Let $H$ be a real Hilbert space with inner product $\langle \cdot , \cdot \rangle$ and norm $\| \cdot \|$. The convex feasibility problem (CFP) is formulated as follows.

If $\cap_{i=1}^{n} C_i \neq \emptyset$, find a point $x^* \in \cap_{i=1}^{n} C_i$,

where $n \geq 1$ is an integer, and each $C_i$ is a nonempty closed convex subset of $H$. It has been proved that the CFP has received so much attention due to its extensive applications in many applied disciplines as diverse as approximation theory, image recovery and signal processing, and so on. A complete and exhaustive study on algorithms and applications for solving the CFP can be found in [3, 5, 12, 13]. As a special case of the CFP, the split feasibility problem can be stated as follows.

The split feasibility problem (SFP) in finite-dimensional Hilbert spaces was first introduced by Censor and Elfving [2]. The SFP is to find

$$x^* \in C \text{ such that } Ax^* \in Q,$$

(1.1)

where $C$ and $Q$ are nonempty closed convex subsets of the Hilbert spaces $H_1$ and $H_2$, respectively, $A : H_1 \to H_2$ is a bounded linear operator. It has been found that the SFP (1.1) can be used in many areas such
as image restoration, computer tomograph, and radiation therapy treatment planning. Some methods have been proposed to solve split feasibility problems; see, for instance, [1, 17, 18, 19].

Note that if the SFP (1.1) is consistent, it is no hard to see that \( x^* \) solves the SFP (1.1) if and only if it solves the fixed point equation

\[
x^* = P_C(I - \gamma A^*(I - P_Q)A)x^*,
\]

where \( P_C \) and \( P_Q \) are the metric projections from \( H_1 \) onto \( C \) and from \( H_2 \) onto \( Q \), respectively, \( \gamma \) is a positive constant and \( A^* \) denotes the adjoint of \( A \) (see [15, Proposition 3.2] for the details). This implies that the SFP (1.1) can be solved by using fixed point algorithms.

In 2013, Moudafi and Al-Shemas [11] introduced the following new split feasibility problem, which is called the split equality fixed point problem (SEFP). Let \( H_1, H_2, H_3 \) be real Hilbert spaces, let \( A : H_1 \to H_3, B : H_2 \to H_3 \) be two bounded linear operators, let \( U : H_1 \to H_1 \) and \( T : H_2 \to H_2 \) be two firmly quasi-nonexpansive mappings. The SEFP in [11] is to

\[
\text{find } x^* \in F(U), \ y^* \in F(T) \text{ such that } Ax^* = By^*. \tag{1.2}
\]

The interest is to cover many situations, for instance, in decomposition methods for PDF's, applications in game theory and in intensity-modulated radiation therapy (IMRT).

For solving the SEFP (1.2), Moudafi and Al-Shemas [11] introduced the following simultaneous iterative method:

\[
\begin{cases}
x_{k+1} = U(x_k - \gamma_k A^*(Ax_k - By_k)), \\
y_{k+1} = T(y_k + \gamma_k B^*(Ax_k - By_k))
\end{cases}
\]

for firmly quasi-nonexpansive mappings \( U \) and \( T \), where \( \gamma_k \in (\epsilon, \frac{2}{\lambda_A + \lambda_B} - \epsilon) \), \( \lambda_A, \lambda_B \) stand for the spectral radii of \( A^*A \) and \( B^*B \), respectively.

In 2016, Zhao and Wang [21] proposed the following viscosity iterative algorithm for solving the SEFP (1.2):

\[
\begin{cases}
u_k = x_k - \gamma_k A^*(Ax_k - By_k), \\
x_{k+1} = \alpha_k f_1(x_k) + (1 - \alpha_k)((1 - w_k)u_k + w_k U(u_k)), \\
v_k = y_k + \gamma_k B^*(Ax_k - By_k), \\
y_{k+1} = \alpha_k f_2(y_k) + (1 - \alpha_k)((1 - w_k)v_k + w_k T(v_k))
\end{cases} \tag{1.3}
\]

where \( f_1 : H_1 \to H_1 \) and \( f_2 : H_2 \to H_2 \) are two contractions, \( U : H_1 \to H_1 \) and \( T : H_2 \to H_2 \) are quasi-nonexpansive. They proved a strong convergence result of the algorithm (1.3) in Hilbert spaces.

Recently, the multiple-set split equality common fixed-point problem (MSECFP) of quasi-nonexpansive mappings studied by Zhao and Wang [20] is to

\[
\text{find } x^* \in \cap_{i=1}^p F(U_i), \ y^* \in \cap_{j=1}^q F(T_j) \text{ such that } Ax^* = By^*, \tag{1.4}
\]

where \( p, q \geq 1 \) are integers. They introduced two mixed cyclic and parallel iterative algorithms for solving the MSECFP (1.4) of quasi-nonexpansive mappings and proved the weak convergence of these two algorithms.

Inspired and motivated by the works mentioned above, we consider a new viscosity iterative algorithm for the MSECFP (1.4) of demicontractive mappings which are generalization of quasi-nonexpansive mappings in Hilbert spaces. Under some mild assumptions we obtain some strong convergence results for solving the MSECFP (1.4) and the SEFP (1.2).

2. Preliminaries

Throughout this paper, we always assume that \( H_1, H_2, H_3 \) are real Hilbert spaces and let \( \mathbb{N} \) and \( \mathbb{R} \) be the set of positive integers and real numbers, respectively. We use \( \to \) and \( \rightharpoonup \) to denote strong and weak convergence, respectively, and \( F(T) \) denotes the set of the fixed points of a mapping \( T \).
Let $C$ be a nonempty closed convex subset of a Hilbert space $H$. The metric (or nearest point) projection $P_C$ from $H$ onto $C$ is defined as follows: Given $x \in H$, the unique point $P_Cx \in C$ satisfies the property

$$
\|x - P_Cx\| = \inf_{y \in C} \|x - y\|.
$$

It is well-known [14] that $P_C$ is a nonexpansive mapping and is characterized by the inequality

$$
P_Cx \in C, \quad \langle x - P_Cx, y - P_Cx \rangle \leq 0, \quad \forall y \in C. \quad (2.1)
$$

Definition 2.1. Let $H$ be a real Hilbert space. A mapping $T : H \to H$ is said to be

1. Lipschitzian, if there exists a constant $\rho > 0$ such that

$$
\|Tx - Ty\| \leq \rho \|x - y\|, \quad \forall x, y \in H,
$$

especially, if $\rho \in (0, 1)$, $T$ is said to be a contraction with constant $\rho$;

2. nonexpansive, if $\|Tx - Ty\| \leq \|x - y\|$, for all $x, y \in H$;

3. quasi-nonexpansive, if $F(T) \neq \emptyset$ and $\|Tx - q\| \leq \|x - q\|$, for all $x \in H$, $q \in F(T)$;

4. firmly nonexpansive, if

$$
\|Tx - Ty\|^2 \leq \|x - y\|^2 - \|(I - T)x - (I - Ty)\|^2, \quad \forall x, y \in H,
$$

or equivalently,

$$
\|Tx - Ty\|^2 \leq \langle x - y, Tx - Ty \rangle, \quad \forall x, y \in H;
$$

5. $\mu$-demicontractive, if $F(T) \neq \emptyset$ and there exists a constant $\mu \in (-\infty, 1)$ such that

$$
\|Tx - q\|^2 \leq \|x - q\|^2 + \mu \|x - Tx\|^2, \quad \forall x \in H, q \in F(T).
$$

Remark 2.2. Notice that every 0-demicontractive mapping is exactly quasi-nonexpansive. In particular, we say that it is quasi-strictly pseudo-contractive [9] if $0 \leq \mu < 1$. Moreover, if $\mu \leq 0$, every $\mu$-demicontractive mapping becomes quasi-nonexpansive. Therefore, it is sufficient to only take $\mu \in (0, 1)$ in (v) of Definition 2.1 in Hilbert spaces.

It is worth noting that the class of demicontractive mappings is more general than the class of quasi-nonexpansive mappings and the class of firmly quasi-nonexpansive mappings.

Definition 2.3. Let $C$ be a nonempty closed convex subset of a real Hilbert space $H$. A mapping $F : C \to H$ is said to be

1. monotone, if $\langle Fx - Fy, x - y \rangle \geq 0$, for all $x, y \in C$;

2. strictly monotone, if $\langle Fx - Fy, x - y \rangle > 0$, for all $x, y \in C, x \neq y$;

3. $\eta$-strongly monotone, if there exists a constant $\eta > 0$ such that

$$
\langle Fx - Fy, x - y \rangle \geq \eta \|x - y\|^2, \quad \forall x, y \in C.
$$

Definition 2.4. Let $H$ be a real Hilbert space. An operator $T : H \to H$ is called demiclosed at origin, if for any sequence $\{x_k\}$ which converges weakly to $x$, and if the sequence $\{Tx_k\}$ converges strongly to 0, then $Tx = 0$. 
As a special case of the demicloseness principle on uniformly convex Banach spaces given by [6], we know that if C is a nonempty closed convex subset of a Hilbert space H, and \( T : C \rightarrow H \) is a nonexpansive mapping, then the mapping \( I - T \) is demiclosed on C. Now the following question is naturally raised: If \( T : C \rightarrow H \) is quasi-nonexpansive, is \( I - T \) still demiclosed on C? The answer is negative even at 0 as follows.

**Example 2.5.** The mapping \( T : [0, 1] \rightarrow [0, 1] \) is defined by

\[
T x = \begin{cases} \frac{x}{5}, & x \in [0, \frac{1}{2}] \\ x \sin \pi x, & x \in (\frac{1}{2}, 1]. \end{cases}
\]

Then T is a quasi-nonexpansive mapping, but \( I - T \) is not demiclosed at 0.

In fact, \( F(T) = \{0\} \). For any \( x \in [0, \frac{1}{2}] \), we have

\[
|Tx - 0| = \left| \frac{x}{5} - 0 \right| \leq |x - 0|,
\]

and for any \( x \in (\frac{1}{2}, 1] \), we have

\[
|Tx - 0| = |x \sin \pi x - 0| \leq |x - 0|.
\]

Thus T is quasi-nonexpansive. Taking \( \{x_n\} \subset (\frac{1}{2}, 1] \) and \( x_n \rightarrow \frac{1}{2} (n \rightarrow \infty) \), we have

\[
|(I - T)x_n| = |x_n[1 - \sin \pi x_n]| \rightarrow 0 (n \rightarrow \infty).
\]

But \( T^{\frac{1}{2}} = \frac{1}{10} \neq \frac{1}{2} \), i.e., \( (1 - T)^{\frac{1}{2}} \neq 0 \), so \( I - T \) is not demiclosed at 0.

**Lemma 2.6 ([10]).** Let T be a \( \mu \)-demicontractive self-mapping on H with \( F(T) \neq \emptyset \) and set \( T_\alpha = (1 - \alpha)I + \alpha T \) for \( \alpha \in [0, 1] \). Then, \( T_\alpha \) is quasi-nonexpansive provided that \( \alpha \in [0, 1 - \mu] \) and

\[
||T_\alpha x - q||^2 \leq ||x - q||^2 - \alpha(1 - \mu - \alpha)||x - Tx||^2, \quad x \in H, \quad q \in F(T).
\]

**Lemma 2.7 ([9, Proposition 2.1]).** Assume C is a closed convex subset of a Hilbert space H. Let \( T : C \rightarrow C \) be a self-mapping of C. If \( T \) is a \( \mu \)-demicontractive mapping (which is also called \( \mu \)-quasi-strict pseudo-contraction in [9]), then the fixed point set \( F(T) \) is closed and convex.

**Lemma 2.8 ([7]).** Assume \( \{s_k\} \) is a sequence of nonnegative real numbers such that

\[
\begin{cases} s_{k+1} \leq (1 - \lambda_k)s_k + \lambda_k \delta_k, \\
\lambda_k \leq s_k - \eta_k + \mu_k,
\end{cases}
\]

where \( \{\lambda_k\} \) is a sequence in \( (0, 1) \), \( \{\eta_k\} \) is a sequence of nonnegative real numbers and \( \{\delta_k\} \) and \( \{\mu_k\} \) are two sequences in \( \mathbb{R} \) such that

(i) \( \sum_{k=1}^{\infty} \lambda_k = \infty \);

(ii) \( \lim_{k \rightarrow \infty} \mu_k = 0 \);

(iii) \( \lim_{k \rightarrow \infty} \eta_k = 0 \) implies \( \lim \sup_{k \rightarrow \infty} \delta_k \leq 0 \) for any subsequence \( \{k_1\} \subset \{k\} \).

Then \( \lim_{k \rightarrow \infty} s_k = 0 \).

**Lemma 2.9 ([8]).** Let X and Y be Banach spaces, A be a continuous linear operator from X to Y. Then A is weakly continuous.

**Lemma 2.10 ([16, Proposition 2.7]).** Let H be a real Hilbert space. Suppose that \( F : H \rightarrow H \) is \( \kappa \)-Lipschitzian and \( \eta \)-strongly monotone over a closed convex set \( C \subset H \). Then, the following VIP(\( F, C \))

\[
\langle y - u^*, F(u^*) \rangle \geq 0, \quad \forall v \in C,
\]

has its unique solution \( u^* \in C \).
3. Main results

In this section, we introduce a new parallel algorithm combining viscosity approximation methods for the MSECFP (1.4) of demicontact mapping and prove strong convergence of the algorithm.

Algorithm 3.1. Let \( f_1 : H_1 \to H_1 \) and \( f_2 : H_2 \to H_2 \) be two contractions with constants \( \rho_1, \rho_2 \in [0, 1) \) and \( \{t_k\} \subset [0, 1) \). Let \( x_0 \in H_1 \), \( y_0 \in H_2 \) be arbitrary and \( p, q \geq 1 \) be integers. Let \( \{\alpha_k\} \subset [0, 1] \) \((0 \leq i \leq p)\) and \( \{\beta_k\} \subset [0, 1] \) \((0 \leq j \leq q)\) such that \( \sum_{i=0}^{p} \alpha_k^i = 1 \) and \( \sum_{j=0}^{q} \beta_k^j = 1 \). Assume that the \( k \)-th iterate \( x_k \in H_1 \), \( y_k \in H_2 \) has been constructed, then we calculate \((k+1)\)-th iterate \((x_{k+1}, y_{k+1})\) the formula

\[
\begin{cases}
  u_k = x_k - \gamma_k A^*(Ax_k - By_k), \\
  x_{k+1} = t_k f_1(x_k) + (1-t_k)(\alpha_k^0 u_k + \sum_{i=1}^{p} \alpha_k^i U_i(u_k)), \\
  v_k = y_k + \gamma_k B^*(Ax_k - By_k), \\
  y_{k+1} = t_k f_2(y_k) + (1-t_k)(\beta_k^0 v_k + \sum_{j=1}^{q} \beta_k^j T_j(v_k)).
\end{cases}
\] (3.1)

Put \( H^* = H_1 \times H_2 \). Define the inner product of \( H^* \) as follows:

\[
\langle (x_1,y_1), (x_2,y_2) \rangle = \langle x_1, x_2 \rangle + \langle y_1, y_2 \rangle, \quad \forall (x_1,y_1), (x_2,y_2) \in H^*.
\]

It is easy to see that \( H^* \) is also a real Hilbert space and

\[
\| (x,y) \| = (\|x\|^2 + \|y\|^2)^{1/2}, \quad \forall (x,y) \in H^*.
\]

Lemma 3.2. Given two bounded linear operators \( A : H_1 \to H_3, B : H_2 \to H_3 \), let \( U_i : H_1 \to H_1 \) \((1 \leq i \leq p)\) and \( T_j : H_2 \to H_2 \) \((1 \leq j \leq q)\) be \( \tau_i \)-demicontactive and \( \theta_j \)-demicontactive, respectively. Assume that the solution set \( \Gamma \) of (1.4) is nonempty. Then \( \Gamma \) is a nonempty closed convex set.

Proof. By Lemma 2.7 we have \( F(T_j) \) \((1 \leq i \leq p)\) and \( F(U_i) \) \((1 \leq j \leq q)\) are both closed convex subsets, and since \( A \) and \( B \) are both linear, it is easy to see that \( \Gamma \) is a closed convex subset in \( H^* \).

Theorem 3.3. Let \( H_1, H_2, H_3 \) be real Hilbert spaces. Given two bounded linear operators \( A : H_1 \to H_3, B : H_2 \to H_3 \), let \( U_i : H_1 \to H_1 \) \((1 \leq i \leq p)\) and \( T_j : H_2 \to H_2 \) \((1 \leq j \leq q)\) be \( \tau_i \)-demicontactive and \( \theta_j \)-demicontactive, respectively. Suppose that \( I - U_i \) \((1 \leq i \leq p)\), \( I - T_j \) \((1 \leq j \leq q)\) are demiclosed at origin and the solution set \( \Gamma \) of the MSECFP (1.4) is nonempty. Assume that the following conditions are satisfied:

(i) \( \rho_1, \rho_2 \in [0, 1/2) \);

(ii) \( \lim_{k \to \infty} t_k = 0 \) and \( \sum_{k=0}^{\infty} t_k = \infty \);

(iii) \( \lim_{k \to \infty} \alpha_k^0 > \tau, \lim_{k \to \infty} \beta_k^0 > \mu \);

(iv) \( \lim_{k \to \infty} \alpha_k^i > 0 \) \((1 \leq i \leq p)\), \( \lim_{k \to \infty} \beta_k^j > 0 \) \((1 \leq j \leq q)\);

(v) \( \gamma_k \in (\varepsilon, \frac{2}{\lambda_A + \lambda_B} - \varepsilon) \),

where \( \tau = \max_{1 \leq i \leq p} \tau_i, \mu = \max_{1 \leq j \leq q} \theta_j, \lambda_A, \lambda_B \) stand for the spectral radiuses of \( A^*A \) and \( B^*B \), respectively and \( \varepsilon > 0 \) is small enough. Then the sequence \( \{(x_k, y_k)\} \) generated by Algorithm 3.1 converges strongly to \((x^*, y^*) \in \Gamma\) which is the unique solution of the following variational inequality problem (VIP)

\[
\langle (1-f_1)x^*, (1-f_2)y^* \rangle, (x,y) - (x^*, y^*) \rangle \geq 0, \quad \forall (x,y) \in \Gamma.
\] (3.2)

Proof. We divide the proof into several steps.

Step 1. The VIP (3.2) has a unique solution \((x^*, y^*) \in \Gamma\).
By Lemma 3.2, we know that $\Gamma$ is a nonempty closed convex subset in $H^*$. Let $F : \Gamma \subset H^* \to H^*$ be defined by

$$F(x, y) = ((I - f_1)x, (I - f_2)y), \quad \forall (x, y) \in \Gamma.$$  

Putting $\rho = \max\{\rho_1, \rho_2\}$, then from the condition (i) we have $\rho \in [0, \frac{1}{2\sqrt{2}})$. For any $(x_1, y_1), (x_2, y_2) \in \Gamma$, since $f_1$ and $f_2$ are two contractions, we have

$$\langle F(x_1, y_1) - F(x_2, y_2), (x_1, y_1) - (x_2, y_2) \rangle = \langle (I - f_1)x_1 - (I - f_1)x_2, (I - f_2)y_1 - (I - f_2)y_2 \rangle - \langle (I - f_2)y_1 - (I - f_2)y_2, x_1 - x_2, y_1 - y_2 \rangle \geq \|x_1 - x_2\|^2 - \|f_1(x_1) - f_1(x_2)\|\|x_1 - x_2\| + \|y_1 - y_2\|^2 - \|f_2(y_1) - f_2(y_2)\|\|y_1 - y_2\| \geq (1 - \rho)(\|x_1 - x_2\|^2 + \|y_1 - y_2\|^2) \geq (1 - \rho)(\|x_1 - x_2\|^2 + \|y_1 - y_2\|^2),$$

which implies that $F$ is $(1 - \rho)$-strongly monotone, and

$$\|F(x_1, y_1) - F(x_2, y_2)\|^2 = \|(I - f_1)x_1 - (I - f_1)x_2, (I - f_2)y_1 - (I - f_2)y_2\|^2 \leq 2(1 + \rho_1^2)|x_1 - x_2|^2 + 2(1 + \rho_2^2)|y_1 - y_2|^2 \leq 2(1 + \rho^2)(\|x_1 - x_2\|^2 + \|y_1 - y_2\|^2),$$

which implies that $F$ is $2(1 + \rho^2)$-Lipschitzian. Therefore, it follows from Lemma 2.10 that the VIP (3.2) has a unique solution $(x^*, y^*) \in \Gamma$.

**Step 2.** The sequences $\{x_n\}$ and $\{y_n\}$ are bounded.

Since $(x^*, y^*) \in \Gamma$, then $x^* \in \cap_{i=1}^{m} F(U_i)$, $y^* \in \cap_{i=1}^{n} F(T_i)$ such that $Ax^* = By^*$. By (3.1) and the definitions of $\lambda_A$ and $\lambda_B$, we have

$$\|u_k - x^*\|^2 = \|x_k - \gamma_k A^*(Ax_k - By_k) - x^*\|^2 = \|x_k - x^*\|^2 - 2\gamma_k \langle x_k - x^*, A^*(Ax_k - By_k) \rangle + \gamma_k^2 \|A^*(Ax_k - By_k)\|^2 \leq \|x_k - x^*\|^2 - 2\gamma_k \langle Ax_k - Ax^*, Ax_k - By_k \rangle + \gamma_k^2 \|Ax_k - By_k\|^2 \leq \|x_k - x^*\|^2 - 2\gamma_k \langle Ax_k - Ax^*, Ax_k - By_k \rangle + \gamma_k^2 \lambda_A \|Ax_k - By_k\|^2,$$

and

$$\|v_k - y^*\|^2 = \|y_k + \gamma_k B^*(Ax_k - By_k) - y^*\|^2 = \|y_k - y^*\|^2 + 2\gamma_k \langle By_k - By^*, Ax_k - By_k \rangle + \gamma_k^2 \|B^*(Ax_k - By_k)\|^2 \leq \|y_k - y^*\|^2 + 2\gamma_k \langle By_k - By^*, Ax_k - By_k \rangle + \gamma_k^2 \lambda_B \|Ax_k - By_k\|^2.$$
By adding the above inequalities and $Ax^* = By^*$, we have
\[
\|u_k - x^*\|^2 + \|v_k - y^*\|^2 \leq \|x_k - x^*\|^2 + \|y_k - y^*\|^2 - \gamma_k[2 - (\lambda_A + \lambda_B)\gamma_k]\|Ax_k - By_k\|^2. \tag{3.3}
\]
Taking $\omega_k = \frac{\alpha_k^i}{1 - \alpha_k^i}$ ($1 \leq i \leq p$) and $\tilde{\omega}_k^j = \frac{\beta_j^i}{1 - \beta_j^i}$ ($1 \leq j \leq q$), we have $\sum_{i=1}^{p} \omega_k^i = 1$ and $\sum_{j=1}^{q} \tilde{\omega}_k^j = 1$ for every $k \geq 0$. Put $\tilde{u}_k = \alpha_k^0 u_k + \sum_{i=1}^{p} \omega_k^i U_i(u_k)$ and $\tilde{v}_k = \beta_k^0 v_k + \sum_{j=1}^{q} \tilde{\omega}_k^j T_j(v_k)$. Then
\[
\tilde{u}_k = \alpha_k^0 u_k + (1 - \alpha_k^0) \sum_{i=1}^{p} \omega_k^i U_i(u_k)
= \sum_{i=1}^{p} \omega_k^i (\alpha_k^0 u_k + (1 - \alpha_k^0) U_i(u_k)). \tag{3.4}
\]
Using Lemma 2.6 for any $i \in \{1, 2, \cdots, p\}$, we have
\[
\|\alpha_k^0 u_k + (1 - \alpha_k^0) U_i(u_k) - x^*\|^2 \leq \|u_k - x^*\|^2 - (1 - \alpha_k^0)(\alpha_k^0 - \tau_i)\|U_i(u_k) - u_k\|^2
\leq \|u_k - x^*\|^2 - (1 - \alpha_k^0)(\alpha_k^0 - \tau)\|U_i(u_k) - u_k\|^2 \tag{3.5}
\]
for all sufficiently large $k$. Thus by (3.4), (3.5), the convexity of $\| \cdot \|^2$ and the condition (iii) we obtain
\[
\|\tilde{u}_k - x^*\|^2 \leq \sum_{i=1}^{p} \omega_k^i \|\alpha_k^0 u_k + (1 - \alpha_k^0) U_i(u_k) - x^*\|^2
\leq \sum_{i=1}^{p} \omega_k^i \|u_k - x^*\|^2 - (1 - \alpha_k^0)(\alpha_k^0 - \tau)\|U_i(u_k) - u_k\|^2
= \|u_k - x^*\|^2 - (1 - \alpha_k^0)(\alpha_k^0 - \tau)\sum_{i=1}^{p} \omega_k^i \|U_i(u_k) - u_k\|^2
= \|u_k - x^*\|^2 - (\alpha_k^0 - \tau)\sum_{i=1}^{p} \alpha_k^i \|U_i(u_k) - u_k\|^2 \tag{3.6}
\]
for all sufficiently large $k$. Similarly, we obtain
\[
\|\tilde{v}_k - y^*\|^2 \leq \|v_k - y^*\|^2 - (\beta_k^0 - \mu) \sum_{j=1}^{q} \beta_k^j \|T_j(v_k) - v_k\|^2 \tag{3.8}
\leq \|v_k - y^*\|^2 \tag{3.9}
\]
for all sufficiently large $k$. It follows from (3.1) and (3.6) that
\[
\|x_{k+1} - x^*\|^2 \leq t_k \|f_1(x_k) - x^*\|^2 + (1 - t_k)\|\tilde{u}_k - x^*\|^2
\leq t_k |p_1| \|x_k - x^*\|^2 + \|f_1(x^*) - x^*\|^2 + (1 - t_k)\|u_k - x^*\|^2
- (\alpha_k^0 - \tau)\sum_{i=1}^{p} \alpha_k^i \|U_i(u_k) - u_k\|^2 \tag{3.10}
\leq 2t_k \rho^2 \|x_k - x^*\|^2 + 2t_k \|f_1(x^*) - x^*\|^2 + (1 - t_k)\|u_k - x^*\|^2
- (1 - t_k)(\alpha_k^0 - \tau)\sum_{i=1}^{p} \alpha_k^i \|U_i(u_k) - u_k\|^2.
\]
Similarly, we obtain
\[
\|y_{k+1} - y^*\|^2 \leq 2t_k \rho^2 \|y_k - y^*\|^2 + 2t_k \|f_2(y^*) - y^*\|^2 + (1 - t_k)\|v_k - y^*\|^2
- (1 - t_k)(\beta_k^0 - \mu) \sum_{j=1}^{q} \beta_k^j \|T_j(v_k) - v_k\|^2. \tag{3.11}
\]
It follows from (3.3), (3.10) and (3.11) that

$$
||x_{k+1} - x^*||^2 + ||y_{k+1} - y^*||^2 \leq 2t_k p^2(||x_k - x^*||^2 + ||y_k - y^*||^2) + 2t_k(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2) + (1 - t_k)(||u_k - x^*||^2 + ||v_k - y^*||^2)
$$

$$
- (1 - t_k)(\alpha_k - \tau) \sum_{i=1}^{p} \alpha_i ||U_i(u_k) - u_k||^2
$$

$$
- (1 - t_k)(\beta_k - \mu) \sum_{j=1}^{q} \beta_j ||T_j(v_k) - v_k||^2
$$

$$
\leq [1 - t_k(1 - 2\rho^2)] (||x_k - x^*||^2 + ||y_k - y^*||^2)
$$

$$
+ 2t_k(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2) - (1 - t_k)\gamma_k [2 - (\lambda_A + \lambda_B)\gamma_k] ||Ax_k - By_k||^2
$$

$$
- (1 - t_k)(\alpha_k - \tau) \sum_{i=1}^{p} \alpha_i ||U_i(u_k) - u_k||^2
$$

$$
- (1 - t_k)(\beta_k - \mu) \sum_{j=1}^{q} \beta_j ||T_j(v_k) - v_k||^2
$$

$$
\leq [1 - t_k(1 - 2\rho^2)] s_k + t_k(1 - 2\rho^2) \frac{2(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2)}{1 - 2\rho^2}.
$$

Then setting $s_k = ||x_k - x^*||^2 + ||y_k - y^*||^2$, we get

$$
s_{k+1} \leq [1 - t_k(1 - 2\rho^2)] s_k + 2t_k(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2)
$$

$$
- (1 - t_k)\gamma_k [2 - (\lambda_A + \lambda_B)\gamma_k] ||Ax_k - By_k||^2
$$

$$
- (1 - t_k)(\alpha_k - \tau) \sum_{i=1}^{p} \alpha_i ||U_i(u_k) - u_k||^2
$$

$$
- (1 - t_k)(\beta_k - \mu) \sum_{j=1}^{q} \beta_j ||T_j(v_k) - v_k||^2
$$

$$
\leq [1 - t_k(1 - 2\rho^2)] s_k + t_k(1 - 2\rho^2) \frac{2(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2)}{1 - 2\rho^2}.
$$

It follows from induction that

$$
s_{k+1} \leq \max(s_0, \frac{2(||f_1(x^*) - x^*||^2 + ||f_2(y^*) - y^*||^2)}{1 - 2\rho^2}), \quad \forall k \geq 0,
$$

i.e., $\{s_k\}$ is bounded. So $\{x_k\}$ and $\{y_k\}$ are also bounded.

**Step 3.** The sequence $\{(x_k, y_k)\}$ converges strongly to $(x^*, y^*)$.

It follows from (3.1) and (3.7) that

$$
||x_{k+1} - x^*||^2 = t_k^2 ||f_1(x_k) - x^*||^2 + 2t_k(1 - t_k) (f_1(x_k) - x^*, \tilde{u}_k - x^*)
$$

$$
+ (1 - t_k)^2 ||\tilde{u}_k - x^*||^2
$$

$$
\leq t_k^2 ||f_1(x_k) - x^*||^2 + t_k(1 - t_k)(||f_1(x_k) - f_1(x^*)||^2 + ||\tilde{u}_k - x^*||^2)
$$

$$
+ (1 - t_k)^2 ||\tilde{u}_k - x^*||^2 + 2t_k(1 - t_k)(f_1(x^*) - x^*, \tilde{u}_k - x^*)
$$

$$
\leq t_k^2 ||f_1(x_k) - x^*||^2 + t_k(1 - t_k)(\rho_1^2 ||x_k - x^*||^2 + ||u_k - x^*||^2)
$$

$$
+ (1 - t_k)^2 ||u_k - x^*||^2 + 2t_k(1 - t_k)(f_1(x^*) - x^*, \tilde{u}_k - x^*)
$$

$$
\leq t_k(1 - t_k)p^2 ||x_k - x^*||^2 + (1 - t_k)||u_k - x^*||^2
$$

$$
+ t_k^2 ||f_1(x_k) - x^*||^2 + 2t_k(1 - t_k)(f_1(x^*) - x^*, \tilde{u}_k - x^*).\)
Similarly we have

\[ \|y_{k+1} - y^*\|^2 \leq t_k(1-t_k)\rho^2\|y_k - y^*\|^2 + (1-t_k)\|\nu_k - y^*\|^2 + t_k^2\|f_2(y_k) - y^*\|^2 + 2t_k(1-t_k)(f_2(y^*) - y^*, \nu_k - y^*). \]  

(3.14)

By (3.3), (3.13) and (3.14) we get

\[
\begin{align*}
    s_{k+1} & \leq t_k(1-t_k)\rho^2(\|x_k - x^*\|^2 + \|y_k - y^*\|^2) \\
    & \quad + (1-t_k)(\|u_k - x^*\|^2 + \|\nu_k - y^*\|^2) \\
    & \quad + t_k^2(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2) \\
    & \quad + 2t_k(1-t_k)((f_1(x^*) - x^*, \tilde{u}_k - x^*) + (f_2(y^*) - y^*, \tilde{v}_k - y^*)) \\
    & \leq [1-t_k(1-(1-t_k)\rho^2)]s_k + t_k^2(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2) \\
    & \quad + 2t_k(1-t_k)((f_1(x^*) - x^*, \tilde{u}_k - x^*) + (f_2(y^*) - y^*, \tilde{v}_k - y^*)) \\
    & = (1-\lambda_k)s_k + \lambda_k \delta_k,
\end{align*}
\]

where \( \lambda_k = t_k(1-(1-t_k)\rho^2) \)

\[
\delta_k = \frac{t_k(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2)}{1-(1-t_k)\rho^2} + \frac{2(1-t_k)((f_1(x^*) - x^*, \tilde{u}_k - x^*) + (f_2(y^*) - y^*, \tilde{v}_k - y^*))}{1-(1-t_k)\rho^2}.
\]

From (3.1), (3.6) and (3.8) we have

\[
\|x_{k+1} - x^*\|^2 \leq t_k\|f_1(x_k) - x^*\|^2 + (1-t_k)\|\tilde{u}_k - x^*\|^2 \\
\leq t_k\|f_1(x_k) - x^*\|^2 + (1-t_k)(\|u_k - x^*\|^2 - (\alpha_0^0 - \tau)\sum_{i=1}^{p}\alpha_k^i\|U_i(u_k) - u_k\|^2),
\]

and

\[
\|y_{k+1} - x^*\|^2 \leq t_k\|f_2(y_k) - y^*\|^2 + (1-t_k)\|\tilde{v}_k - y^*\|^2 \\
\leq t_k\|f_2(y_k) - y^*\|^2 + (1-t_k)(\|v_k - y^*\|^2 - (\beta_0^0 - \mu)\sum_{j=1}^{q}\beta_k^j\|T_j(v_k) - v_k\|^2),
\]

which together with (3.3) imply that

\[
\begin{align*}
    s_{k+1} & \leq \|u_k - x^*\|^2 + \|v_k - y^*\|^2 + t_k(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2) \\
    & \quad - (1-t_k)((\alpha_0^0 - \tau)\sum_{i=1}^{p}\alpha_k^i\|U_i(u_k) - u_k\|^2 \\
    & \quad + (\beta_0^0 - \mu)\sum_{j=1}^{q}\beta_k^j\|T_j(v_k) - v_k\|^2) \\
    & \leq s_k + t_k(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2) - \gamma_k(2-(\lambda_A + \lambda_B)\gamma_k) \\
    & \quad \times \|\lambda_A x_k - B y_k\|^2 - (1-t_k)((\alpha_0^0 - \tau) \\
    & \quad \times \sum_{i=1}^{p}\alpha_k^i\|U_i(u_k) - u_k\|^2 + (\beta_0^0 - \mu)\sum_{j=1}^{q}\beta_k^j\|T_j(v_k) - v_k\|^2) \\
    & \leq s_k - \eta_k + \mu_k,
\end{align*}
\]

(3.16)
where $\mu_k = t_k(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2)$,

$$
\eta_k = \gamma_k[2 - (\lambda_A + \lambda_B)\gamma_k]\|Ax_k - By_k\|^2 + (1 - t_k)((\alpha_k^0 - \tau) \times \sum_{i=1}^p \alpha_k^i \|U_i(u_k) - u_k\|^2 + (\beta_k^0 - \mu) \sum_{j=1}^q \beta_k^j \|T_j(v_k) - v_k\|^2).
$$

It follows that $\sum_{k=0}^\infty \lambda_k$ and $\lim_{k \to \infty} \mu_k = 0$ due to the condition (ii) and the boundedness of $\{x_k\}$ and $\{y_k\}$.

Next we show that $\lim_{k \to \infty} \eta_{k_1} = 0$ implies that $\limsup_{k \to \infty} \delta_{k_1} \leq 0$ for any $\{k_1\} \subset \{k\}$. Indeed, for any $\{k_1\} \subset \{k\}$ and $\lim_{k \to \infty} \eta_{k_1} = 0$, by the conditions (ii)-(v), for any $i \in \{1, 2, \cdots, p\}$, $j \in \{1, 2, \cdots, q\}$ we have

$$
\lim_{k \to \infty} \|Ax_k - By_{k_1}\| = \lim_{k \to \infty} \|u_k - U_i(u_k)\| = \lim_{k \to \infty} \|v_k - T_j(v_k)\| = 0.	ag{3.17}
$$

Then we have

$$
\lim_{k \to \infty} \|u_k - x_k\| = \lim_{k \to \infty} \gamma_k \|A^*(Ax_k - By_{k_1})\| = 0, \tag{3.18}
$$

$$
\lim_{k \to \infty} \|v_k - y_{k_1}\| = \lim_{k \to \infty} \gamma_k \|B^*(Ax_k - By_{k_1})\| = 0. \tag{3.19}
$$

For any $(\bar{x}, \bar{y}) \in \omega_{w}(x_{k_1}, y_{k_1})$, from (3.18) and (3.19) we have $(\bar{x}, \bar{y}) \in \omega_{w}(u_{k_1}, v_{k_1})$. Due to the demiclosedness of $1 - U_i (1 \leq i \leq p)$ and $1 - T_j (1 \leq j \leq q)$ at origin and (3.17) we get $\bar{x} \in \cap_{i=1}^p F(U_i)$ and $\bar{y} \in \cap_{j=1}^q F(T_j)$. It follows from Lemma 2.9 that $A\bar{x} - B\bar{y} \in \omega(w(Ax_{k_1} - By_{k_1}))$, which together with the weakly lower semicontinuity of the norm and (3.17) implies

$$
\|A\bar{x} - B\bar{y}\| \leq \liminf_{k \to \infty} \|Ax_k - By_{k_1}\| = 0.
$$

Hence $(\bar{x}, \bar{y}) \in \Gamma$, i.e., $\omega_{w}(x_{k_1}, y_{k_1}) \subset \Gamma$. It is easy to see that $\lim_{k \to \infty}(1 - (1 - t_k)\rho^2) = 1 - \rho^2$ and $\lim_{k \to \infty} t_k(\|f_1(x_k) - x^*\|^2 + \|f_2(y_k) - y^*\|^2) = 0$. So finally we only need to prove

$$
\limsup_{k \to \infty}(f_1(x_k) - x^*, \bar{u}_k - x^*) + \sum_{i=1}^p \alpha_k^i (U_i(u_k) - x^*)
$$

$$
+ \sum_{j=1}^q \beta_k^j (T_j(v_k) - y^*) \leq \limsup_{k \to \infty}(f_1(x_k) - x^*, \alpha_k^0 U_k - x^*)
$$

$$
+ \sum_{i=1}^p \alpha_k^i (U_i(u_k) - x_k^*)
$$

$$
+ \sum_{j=1}^q \beta_k^j (T_j(v_k) - y_k^*)
$$

$$
\leq \limsup_{k \to \infty}(f_1(x_k) - x^*, x_k - x^*) + (f_2(y_k) - y^*, y_k - y^*).	ag{3.20}
$$

From (3.17)-(3.19), for any $i \in \{1, 2, \cdots, p\}$, $j \in \{1, 2, \cdots, q\}$, we have

$$
\lim_{k \to \infty} \|U_i(u_k) - x_k\| = \lim_{k \to \infty} \|T_j(v_k) - y_k\| = 0,
$$

furthermore, by (3.18) and (3.19) we obtain

$$
\limsup_{k \to \infty}(f_1(x_k) - x^*, \bar{u}_k - x^*) + (f_2(y_k) - y^*, \bar{v}_k - y^*)
$$

$$
= \limsup_{k \to \infty}(f_1(x_k) - x^*, \alpha_k^0 U_k + \sum_{i=1}^p \alpha_k^i U_i(u_k) - x^*)
$$

$$
+ (f_2(y_k) - y^*, \beta_k^0 v_k)
$$

$$
+ \sum_{j=1}^q \beta_k^j (T_j(v_k) - y^*) \leq \limsup_{k \to \infty}(f_1(x_k) - x^*, \alpha_k^0 x_k + \sum_{i=1}^p \alpha_k^i x_k - x^*)
$$

$$
+ (f_2(y_k) - y^*, \beta_k^0 y_k + \sum_{j=1}^q \beta_k^j y_k - y^*)
$$

$$
+ \limsup_{k \to \infty}(f_1(x_k) - x^*, \alpha_k^0 (u_k - x_k) + \sum_{i=1}^p \alpha_k^i (U_i(u_k) - x_k))
$$

$$
+ \limsup_{k \to \infty}(f_2(y_k) - y^*, \beta_k^0 (v_k - y_k) + \sum_{j=1}^q \beta_k^j (T_j(v_k) - y_k)) \leq \limsup_{k \to \infty}(f_1(x_k) - x^*, x_k - x^*) + (f_2(y_k) - y^*, y_k - y^*).
$$
By the boundedness of \(\{(x_{k_i}, y_{k_i})\}\) in \(H^*\), there exists a point \((p^*, q^*) \in H^*\) and a subsequence \(\{(x_{k_i'}, y_{k_i'})\}\) of \(\{(x_{k_i}, y_{k_i})\}\) in \(H^*\) such that \((x_{k_i'}, y_{k_i'}) \rightharpoonup (p^*, q^*)\) and
\[
\limsup_{l \to \infty} \langle f_1(x^*) - x^*, x_{k_{l}} - x^* \rangle + \langle f_2(y^*) - y^*, y_{k_{l}} - y^* \rangle = \lim_{l \to \infty} \langle f_1(x^*) - x^*, x_{k_{l}}' - x^* \rangle + \langle f_2(y^*) - y^*, y_{k_{l}}' - y^* \rangle.
\]
(3.21)

Then \((p^*, q^*) \in \omega_W(x_{k_{1}}, y_{k_{1}}).\) Similar to the proof of \((\bar{x}, \bar{y}) \in \Gamma\), we have \((p^*, q^*) \in \Gamma\). Thus by (3.2), (3.20) and (3.21) we obtain
\[
\limsup_{l \to \infty} \langle f_1(x^*) - x^*, \bar{u}_{k_{l}} - x^* \rangle + \langle f_2(y^*) - y^*, \bar{v}_{k_{l}} - y^* \rangle \leq \lim_{l \to \infty} \langle f_1(x^*) - x^*, x_{k_{l}}' - x^* \rangle + \langle f_2(y^*) - y^*, y_{k_{l}}' - y^* \rangle = \langle (1 - f_1)x^* - (1 - f_2)y^*, (p^*, q^*) - (x^*, y^*) \rangle \leq 0,
\]
i.e., \(\limsup_{l \to \infty} \delta_{k_{l}} \leq 0\). Therefore it follows from Lemma 2.8 that \(\lim_{k \to \infty} s_k = 0\), that is
\[
\lim_{k \to \infty} (\|x_k - x^*\|^2 + \|y_k - y^*\|^2) = 0,
\]
which implies that \(\{(x_k, y_k)\}\) generated by Algorithm 3.1 converges strongly to \((x^*, y^*) \in \Gamma\) which is the unique solution of the VIP (3.2).

Take \(U_1 = U_2 = \cdots = U_p = U, T_1 = T_2 = \cdots = T_q = T\). Then Algorithm 3.1 reduces to the following algorithm:

\[\text{Algorithm 3.4.}\] Let \(f_1 : H_1 \to H_1\) and \(f_2 : H_2 \to H_2\) be two contractions with constants \(\rho_1, \rho_2 \in [0, 1]\) and \(\{t_k\} \subset [0, 1]\). Let \(x_0 \in H_1, y_0 \in H_2\) be arbitrary. Let \(\{\alpha_k\} \subset [0, 1]\) and \(\{\beta_k\} \subset [0, 1]\). Assume that the \(k\)-th iterate \(x_k \in H_1, y_k \in H_2\) has been constructed, then we calculate \((k+1)\)-th iterate \((x_{k+1}, y_{k+1})\) via the formula

\[
\left\{
\begin{array}{l}
 u_k = x_k - \gamma_k A^* (Ax_k - By_k), \\
x_{k+1} = t_k f_1(x_k) + (1-t_k)(\alpha_k u_k + (1-\alpha_k)U(u_k)), \\
v_k = y_k + \gamma_k B^* (Ax_k - By_k), \\
y_{k+1} = t_k f_2(y_k) + (1-t_k)(\beta_k v_k + (1-\beta_k)T(v_k)).
\end{array}
\right.
\]

By Theorem 3.3, we obtain the following result.

\[\text{Corollary 3.5.}\] Let \(H_1, H_2, H_3\) be real Hilbert spaces. Given two bounded linear operators \(A : H_1 \to H_3, B : H_2 \to H_3\), let \(U : H_1 \to H_1\) and \(T : H_2 \to H_2\) be \(\tau\)-demicorntractive and \(\mu\)-demicorntractive, respectively. Suppose that \(I - U, I - T\) are demiclosed at origin and the solution set \(\Gamma\) of the SEFP (1.2) is nonempty. Assume that the following conditions are satisfied:

(i) \(\rho_1, \rho_2 \in [0, \frac{1}{\sqrt{2}}]\);

(ii) \(\lim_{k \to \infty} t_k = 0\) and \(\sum_{k=0}^{\infty} t_k = \infty\);

(iii) \(\tau < \inf_{k \to \infty} \alpha_k \leq \sup_{k \to \infty} \alpha_k < 1\);

(iv) \(\mu < \inf_{k \to \infty} \beta_k \leq \sup_{k \to \infty} \beta_k < 1\);

(v) \(\gamma_k \in (\varepsilon, \frac{1}{\lambda_A + \lambda_B} - \varepsilon)\),

where \(\lambda_A, \lambda_B\) stand for the spectral radiuses of \(A^* A\) and \(B^* B\), respectively and \(\varepsilon > 0\) is small enough.

Then the sequence \(\{(x_k, y_k)\}\) generated by Algorithm 3.4 converges strongly to a solution \((x^*, y^*)\) of the SEFP (1.2) which is the unique solution of the VIP (3.2).

If \(\mu = \tau = 0\), since every 0-demicontractive mapping is quasi-nonexpansive, from Corollary 3.5 we also have the following corollary.
Corollary 3.6. Let $H_1, H_2, H_3$ be real Hilbert spaces. Given two bounded linear operators $A : H_1 \to H_2, B : H_2 \to H_3$, let $U : H_1 \to H_1$ and $T : H_2 \to H_2$ ($1 \leq j \leq q$) be quasi-nonexpansive with the solution set $\Gamma$ of the SEFP (1.2) is nonempty. Suppose that $I - U, I - T$ are demiclosed at origin. Assume that the following conditions are satisfied:

(i) $\rho_1, \rho_2 \in [0, \frac{1}{\sqrt{2}}]$;

(ii) $\lim_{k \to \infty} t_k = 0$ and $\sum_{k=0}^{\infty} t_k = \infty$;

(iii) $0 < \lim \inf_{k \to \infty} \alpha_k \leq \lim \sup_{k \to \infty} \alpha_k < 1$;

(iv) $0 < \lim \inf_{k \to \infty} \beta_k \leq \lim \sup_{k \to \infty} \beta_k < 1$;

(v) $\gamma_k \in (0, \frac{2}{\lambda_A + \lambda_B} - \varepsilon)$,

where $\lambda_A, \lambda_B$ stand for the spectral radii of $A^*A$ and $B^*B$, respectively and $\varepsilon > 0$ is small enough. Then the sequence $\{(x_k, y_k)\}$ generated by Algorithm 3.4 converges strongly to a solution $(x^*, y^*)$ of the SEFP (1.2) which is the unique solution of the VIP (3.2).

Remark 3.7. Theorem 3.3 extends and develops [21, Theorem 3.2] from the following aspects:

(a) Two quasi-nonexpansive mappings $U$ and $T$ are extended to two finite family of demicontractive mappings $\{U_i\}_{i=1}^{p}$ and $\{T_j\}_{j=1}^{q}$.

(b) The parameter sequence $\{\omega_k\}$ be replaced by two different parameter sequences $\{\alpha_k^i\}$ and $\{\beta_k^j\}$.

(c) The split equality fixed point problem is extended to the multiple-set split equality common fixed-point problem.

(d) The authors did not give the proof of unique solution of the VIP (3.2) in [21], which leads to an incomplete proof. In this paper, we prove it (see Step 1 in the proof). And the VIP (3.2) in this paper is also more general than that in [21].

Now first we shall give an example which satisfies all the conditions of the solution set $\Gamma$ of the MSECFP (1.4), the mappings $\{U_i\}_{i=1}^{p}$, and $\{T_j\}_{j=1}^{q}$ in Theorem 3.3.

Example 3.8. Let $H_1 = H_2 = H_3 = \ell_2$ and let $i \in \{1, 2, \cdots, p\}$ and $j \in \{1, 2, \cdots, q\}$ be arbitrarily fixed. Let $U_i, T_j : \ell_2 \to \ell_2$ be defined by $U_i x = \frac{-2i}{\ell} x$ and $T_j x = -(2j + 1)x$ for all $x \in \ell_2$. Then it is easy to see that $\cap_{i=1}^{p} F(U_i) = \{0\} = \cap_{j=1}^{q} F(T_j)$ and $A_0 = 0 = B_0$. Thus $\Gamma = \{(0, 0)\} \neq \emptyset$. Also $U_i$ is $\tau_i$-demicontractive and $T_j$ is $\theta_j$-demicontractive, where $\tau_i = \frac{2}{(2i+1)}$ and $\theta_j = \frac{1}{(2j+1)}$, then $I - U_i$ and $I - T_j$ are demiclosed at 0.

Indeed, for any $i \in \{1, 2, \cdots, p\}$ and $j \in \{1, 2, \cdots, q\}$, similar to the proof of Example 2.5 in [4], we have $U_i$ is $\tau_i$-demicontractive and $T_j$ is $\theta_j$-demicontractive. Meanwhile, $I - U_i$ is obviously demiclosed at 0. For, whenever $(x_n)$ is any sequence in $\ell_2$ such that $x_n \rightharpoonup x \in \ell_2$ and $\|x_n - U_i x_n\| \to 0$, we readily see that $x = 0 \in F(U_i)$. Also, $I - T_j$ are demiclosed at 0.

Next we give an example which satisfies the conditions (iii)-(iv) in Theorem 3.3.

Example 3.9. For $k \geq 0$, we can take $\alpha_k^0 = \alpha_k^1 = \alpha_k^2 = \cdots = \alpha_k^p = 1 - \frac{\tau}{p+1} - \frac{1-\tau}{p(p+2)(k+1)}$, $\beta_k = \beta_k^2 = \cdots = \beta_k^q = 1 - \frac{\mu}{q+1} - \frac{1-\mu}{q(q+2)(k+1)}$.

4. Numerical examples

In this section, in order to demonstrate the effectiveness, realization and convergence of the algorithm of Theorem 3.3, we consider the following example in $(\mathbb{R}, \| \cdot \|)$.

Example 4.1 (Numerical Example). Let $H_1 = H_2 = H_3 = \mathbb{R}$ and $p = q = 3$. Let $f_1, f_2 : \mathbb{R} \to \mathbb{R}$ be defined by $f_1(x) = f_2(x) = \frac{x}{2}$. Let $A, B : \mathbb{R} \to \mathbb{R}$ be defined by $Ax = Bx = -x$. For any $i, j \in \{1, 2, 3\}$, let $U_i, T_j : \mathbb{R} \to \mathbb{R}$ be defined by $U_i x = -2ix$ and $T_j x = -(2j + 1)x$, respectively. Let the sequence $\{(x_k, y_k)\}$ be generated iteratively by (3.1), where $\alpha_k^0 = \frac{2}{5}, \alpha_k^1 = \alpha_k^2 = \frac{1}{7}, \beta_k^0 = \frac{4}{7}, \beta_k^1 = \beta_k^2 = \beta_k^3 = \frac{1}{3}$ and $t_k = \frac{1}{k+2}$ for all $k \geq 0$. Then, the sequence $\{(x_k, y_k)\}$ converges strongly to $(0,0)$.
Solution: It is easy to see that \( \cap_{i=1}^{3} F(U_i) = \{0\} = \cap_{j=1}^{3} F(T_j) \) and \( A0 = 0 = B0 \). Thus \( \Gamma = \{(0, 0)\} \neq \emptyset \). Also \( U_i \) is \( \tau_i \)-demicontractive and \( T_j \) is \( \theta_j \)-demicontractive, where \( \tau_i = \frac{2i-1}{2i+1} \) and \( \theta_j = \frac{j}{j+1} \), and \( I - U_i \) and \( I - T_j \) are demiclosed at 0, \( i, j = 1, 2, 3 \). Then \( \tau = \frac{1}{2} \) and \( \mu = \frac{3}{4} \). From the definition of \( \Lambda \) and \( B \), \( \lambda_A = \lambda_B = 1 \), we choose \( \gamma_k = \gamma = \frac{1}{2} \). It can be observed that all the assumptions of Theorem 3.3 are satisfied.

Then the scheme (3.1) can be simplified as

\[
\begin{align*}
x_{k+1} &= \frac{2k+9}{14(k+2)} x_k + \frac{k+1}{7(k+2)} y_k, \\
y_{k+1} &= \frac{8k+5}{8(k+2)} x_k + \frac{k+5}{8(k+2)} y_k, \quad k \geq 0.
\end{align*}
\]

Utilizing the scheme (4.1), we report the numerical results in Table 1 and Table 2. In addition, Figure 1 also demonstrates Theorem 3.3.

5. Conclusion

In this work, we study the MSECFP (1.4) which is a generalization of the SEFP (1.2). In order to obtain the strong convergence result, we introduce a new parallel algorithm combining viscosity approximation methods for the MSECFP (1.4) of demicontractive mappings in Hilbert spaces. The results we obtained mainly generalize and extend the ones in [21] from two quasi-nonexpansive mappings to two finite family of demicontractive mappings and from the SEFP (1.2) to the MSECFP (1.4). Meanwhile, we give the numerical example to demonstrate the effectiveness, realization and convergence of our algorithm. We desire that the results presented here will be useful and valuable for researchers who study the branch of split feasibility problems and related applications.
